## Design Summary

The general architecture of our software consists of a client (The user's web browser) interacting with a server, which updates its database upon a client requesting to make a post. The post editor, which is accessible through the home page, is responsible for the generation of posts, which are objects that reference an html file. The editor is the object with the most functionalities, and is responsible for translating the user's inputs into a unique web page coupled with CSS formatting and resources such as images and sound clips.

Another significant object in the class diagram is the map. The landing page will display a map, and users will have the ability to pan, zoom, and click on posts displayed on the map. In order to display posts, the map will encapsulate numerous 'post' objects. A post is a simple data structure that contains a filepath to the web page and associated resources, as well as other data like creation date and contributors.

The 'User' object is for user registration. A 'User' will not necessarily be the one to "make" a post, because posts should be able to be made anonymously, without the need for registration. Its purpose is to associate posts with their user and contributors.

## Design Rationale

- Changed 'Image', 'Sound' into a more generic 'Element' object. Element follows a "type class" pattern in which the class contains a variable that indicates its type. In this case, the object's type will be indicated by a string, such as "image."
